

# Wind Tunnel Wing Modeling with **Neo**<sup>®</sup> Stereolithography and **Somos**<sup>®</sup> PerFORM<sup>™</sup>

A practical application overview based on wind tunnel testing at Embry-Riddle Aeronautical University

This wind tunnel test model manufacturing approach isn't limited to aircraft wings. The same workflow applies to planes and UAVs, drones, wind turbines, and racing cars. Anywhere teams need accurate geometry and airflow data and the ability to iterate designs quickly.

## The Challenge

Wind tunnel models have to strike a careful balance. They need to be stiff enough to handle loading and mounting, have a surface finish suitable for aerodynamic testing, and avoid excessive laser reflection when using optical techniques like Particle Image Velocimetry (PIV), all without becoming heavy or slow to produce. At Embry-Riddle Aeronautical University (ERAU), CNC-machined sub-scale wings typically take 3-4 weeks after CAD finalization, and metallic surfaces can create laser reflections that interfere with optical measurements.

## The Approach

To shorten lead times and improve test readiness, ERAU produced three wing models using a **Neo**<sup>®</sup>800 printer and **Somos**<sup>®</sup> PerFORM<sup>™</sup> resin. From finalized CAD, all three wings were printed in just over 47 hours, with material costs of around \$4,350 and minimal technician involvement thanks to automated cleaning. One wing printed in orange **Somos**<sup>®</sup> PerFORM<sup>™</sup> Reflect resin did not require a matt black coating, helping reduce laser reflection for PIV without additional surface treatment.

~90% faster

Model fabrication  
vs CNC machining

47 hours,  
2 minutes

Total print time for three copies

~\$4,350

Resin cost for all three wings

3X load

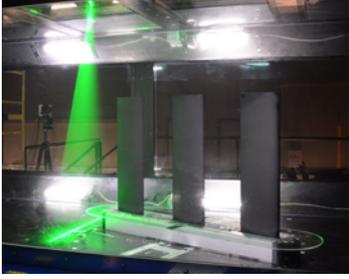

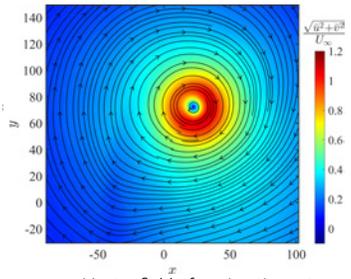

Passed static testing

1-2 hours

Post-processing time for surface  
preparation for laser test
